

WebRTC Browser Calling — Fix & Test Summary

Real-world test follow-up · 28 September 2026 · browser-calling-5194.twil.io

Brett's 17-scenario real-world test pass surfaced five reliability issues to fix before a limited customer trial. All five have been addressed in [assets/index.html](#) and individually verified against the live Twilio deployment.

Fixes & Test Results

#	Issue	Fix	Result
1	Mobile calls locked to speakerphone, no way to switch	Output-device toggle. Desktop: full switching via setSinkId . Android: falls back to switching the <i>microphone</i> , which also flips the audio route (setSinkId isn't supported on mobile browsers).	Confirmed — desktop & Android (headset only) See limitation below re: earpiece.
2	Mic denial fails silently, no error shown	Pre-flight mic permission check; clear on-screen banner with platform-specific recovery steps (iOS/Android/desktop); Try Again button.	Confirmed working
3	Wifi → cellular handoff drops the call	Wired up the Voice SDK's reconnecting/reconnected events, previously unhandled, so the UI reflects the handoff instead of the call silently ending.	Confirmed working
4	Refreshing the browser mid-call drops the call	Leave-confirmation prompt on refresh/close; “tap to reconnect” banner shown on reload, tracked via sessionStorage tied to a genuine unload (pagehide) rather than any call-end event.	Confirmed working (two related bugs found & fixed during testing — see notes)
5	Desktop audio quality rated 3/5 vs WhatsApp/Meet	Set edge=sydney (routes via Twilio's NZ-local edge instead of default region selection) and explicit echo-cancellation / noise-suppression / auto-gain constraints.	Deferred — subjective, for Brett to re-judge by ear

Known Platform Limitation

“**Switch to earpiece**” **cannot be delivered on mobile web at all**. This was confirmed via a still-open Chromium issue (crbug 41276355): Chrome for Android exposes no API for a web page to route WebRTC audio to the earpiece — only speakerphone or an already-connected headset are reachable. iOS Safari exposes no audio-routing control to web pages whatsoever. The fix above is the practical ceiling for a browser-only tool; true earpiece support would require a native app wrapper, which was out of scope.

Next Steps

- Brett to re-run the desktop audio-quality comparison (Chrome & Safari) against WhatsApp/Meet.
